

# Calculations of de Haas van Alphen frequencies: an ab initio approach

Simon Blackburn, Michel Côté  
Université de Montréal, Canada

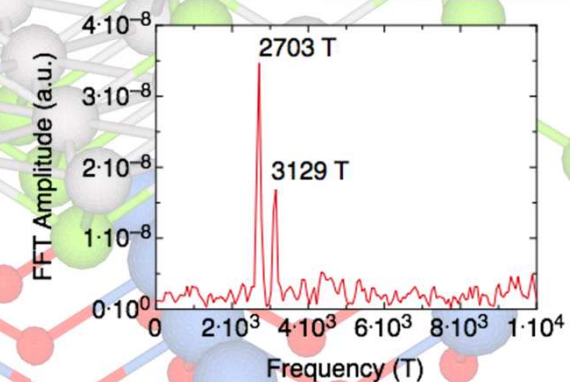

# Plan

- Reminder of the theory
- MLWF
- Code explanation
- Iron pnictides superconductors
- Results
- Magnetic Breakdown

# Experiment

- Sample in a magnetic field
- Torque on the cantilever measures the sample's magnetization
- Oscillations are important!

# Semi-classical equations

- Bohr-Sommerfeld quantization

$$2\pi j = \Gamma + \frac{\hbar c}{eB} A$$

Constant  $\rightarrow \Gamma$

Integer  $\rightarrow 2\pi j$

$$F = \left( \Delta \frac{1}{B} \right)^{-1} = \frac{c\hbar}{2\pi e} A$$

Orbit area  $\rightarrow A$

- Frequencies are a measure of the Fermi surface!
- Only extrema contribute.

# Precision

- Typical ab initio calculation for copper: 6x6x6 k-points
- Too few points to calculate the area of a cross-section precisely
- We need interpolation.
- No need to sample all the Brillouin zone: we only need information on a plane normal to the magnetic field.

# Plan

- Results
- Magnetic Breakdown

# MLWF

- From Abinit -> Wannier90
- Generalized Wannier function:

$$|u_{n\mathbf{k}}\rangle \rightarrow \sum_m U_{mn}^{(\mathbf{k})} |u_{m\mathbf{k}}\rangle$$

- With  $U^{(\mathbf{k})}$  defined such that the spread is minimized<sup>1,2</sup>

$$\sum_n \sum_{\mathbf{k}} \langle u_{n\mathbf{k}} | r^2 | u_{n\mathbf{k}} \rangle - |\langle u_{n\mathbf{k}} | \mathbf{r} | u_{n\mathbf{k}} \rangle|^2$$

- The Hamiltonian in this rotated basis ( $U$ ) is no longer diagonal:

$$\epsilon_{n\mathbf{k}} \delta_{nm} \rightarrow H_{nm}(\mathbf{k})$$

1. Marzari N. and Vanderbilt D., PRB **56**, 12847 (1997)

2. Souza I., Marzari N. and Vanderbilt D., PRB **65**, 035109 (2001)

# MLWF (2)

- Fourier transform :  $H(\mathbf{k}) \rightarrow H(\mathbf{R})$
- Since the basis is localized,  $H(\mathbf{R})$  converges to zero quickly.
- Can be interpolated on an arbitrary point in k-space (called  $\mathbf{q}$ ):

$$H(\mathbf{R}) \rightarrow H(\mathbf{q})$$

- This method is used to calculate the band energies (eigenvalues of  $H(\mathbf{q})$  on a plane normal to the magnetic field)

# Getting a faster interpolation

$$H(\mathbf{q}) = \sum_{\mathbf{R}} e^{i\mathbf{q}\cdot\mathbf{R}} H(\mathbf{R})$$

- Number of  $\mathbf{R}$  = number of k-points in the ABINIT calculations
- Size of the Hamiltonian = number of Wannier functions
  - Tuned by rejecting low (and high) energy state
- Careful about reproducing correctly the FS

# Plan

- Reminder of the theory
- MLWF
- Code explanation
- Iron pnictides superconductors
- Results
- Magnetic Breakdown

# Code: dHvA.py

- Input:
  - $H(\mathbf{R})$  from Wannier90
  - Direction for the magnetic field
  - Option for the Fermi surface slice
- Output:
  - Energy of the plane
  - Possible orbits (open and close)
  - dHvA frequencies (area of closed orbits)
- Going further:
  - Relative intensity of the signal
  - Effective mass

# Slicing the Fermi surface

- Periodic boundary conditions:
  - Finds all the possible orbits
  - Force a specific direction for  $B$
  - Unable to calculate efficiently the area of a specific orbit (too much useless information)
- ‘Manual’ choice
  - Manually choose the direction of the magnetic field, the size and origin of the plane
  - Cannot find an orbit (need to know its position)
  - Much more accurate (useless information is cut out)

# Periodic boundary condition: example BCT crystal

- For a magnetic field in the  $[\cos\theta \ 0 \ \sin\theta]$  direction

$$(\mathbf{a}_1 \ \mathbf{a}_2 \ \mathbf{a}_3) = \begin{pmatrix} -a/2 & a/2 & a/2 \\ a/2 & -a/2 & a/2 \\ c/2 & c/2 & -c/2 \end{pmatrix} \quad (\mathbf{b}_1 \ \mathbf{b}_2 \ \mathbf{b}_3) = \begin{pmatrix} 0 & \tilde{a}/2 & \tilde{a}/2 \\ \tilde{a}/2 & 0 & \tilde{a}/2 \\ \tilde{c}/2 & \tilde{c}/2 & 0 \end{pmatrix}$$

- For y direction, take a segment of length  $\tilde{a}$

- For x&z:

$$(L \cos \theta \ 0 \ L \sin \theta) = n_1 \mathbf{b}_1 + n_2 \mathbf{b}_2 + n_3 \mathbf{b}_3$$

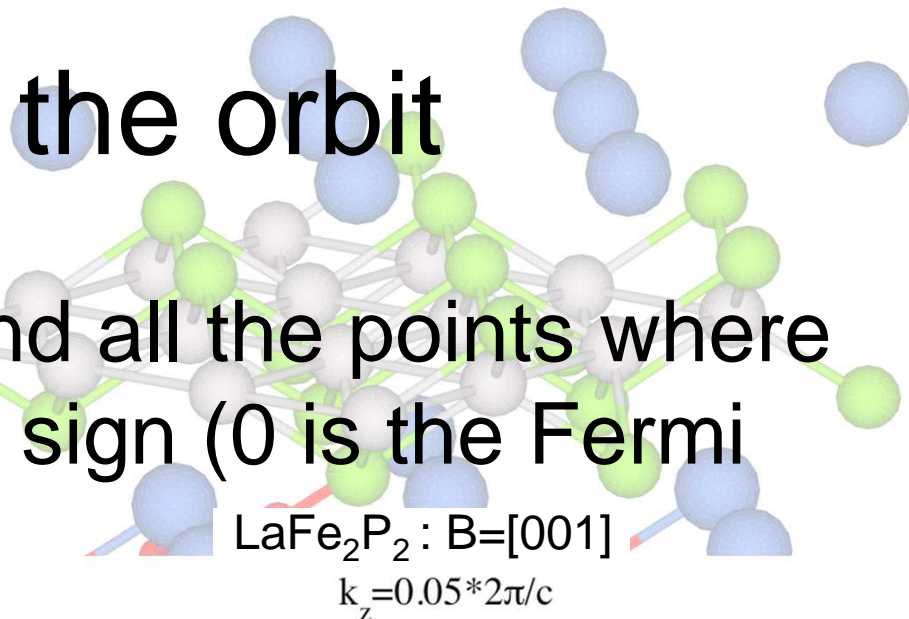

$$\tan \theta = \frac{\tilde{c} n_1 + n_3}{\tilde{a} n_3 - n_1} = \frac{a p}{c q}$$

# $H(q)$ and diagonalize

- Calculate  $H(q)$  for every point on the plane
- Done in a C module: more efficient
- Only interested in a limited set of bands (do not store those not crossing the Fermi level)
- Suppose that each band can be treated separately (disconnected pieces of the FS)

# Finding the orbit

- For a given band, find all the points where the energy changes sign (0 is the Fermi level)
- Connect the dots
- Calculate the area
- Converge!

# Shifting the plane

- Shift the origin of the plane
- Find the extremum: these are the dHvA frequencies
- Intensity (finite difference):

$$I \propto \left( \frac{\partial^2 A}{\partial k_B^2} \right)^{-1/2}$$

- Effective cyclotron mass (finite difference):

$$m^* = \frac{\hbar^2}{2\pi} \left( \frac{\partial A}{\partial E_F} \right)$$

# Test case: copper

- For a magnetic field in the [111] direction

de Haas van Alphen Frequencies: Copper  
Magnetic Field in the [111] direction

Band structure near the crossing

Zoom near the crossing

# Conclusion

- We presented a novel way of calculating dHvA frequencies using maximally localized Wannier function
  - Accurate
  - Low computational cost
- Results for various iron pnictides:  $\text{LaFe}_2\text{P}_2$ ,  $\text{CeFe}_2\text{P}_2$ ,  $\text{BaRh}_2\text{P}_2$ ,  $\text{BaIr}_2\text{P}_2$
- If 2 (or more) bands are almost degenerate at the Fermi level, the electron orbit is reconstructed (breakdown of the semi-classical equation of motion)
